

Unit: DESIGN

Monday, February 25, 2019 2:11 PM

- **Modular Design**

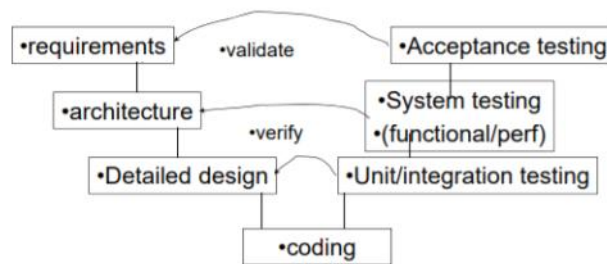

- A module is an implementation unit that provides a coherent set of responsibilities
- Coupling is a measure of how modules are interconnected, high coupling means lots of interconnections and high is bad.

- High coupling is bad because
 - if you change one module that causes a ripple effect
 - Assembly of modules requires more work
 - Module is harder to reuse and test since too much included
- Cohesion is a measure of how strongly-related or focused the responsibilities of a single module are
- Low cohesion is bad:
 - Difficult to understand modules
 - Difficult to maintain a system because change in module mean will have to change other modules
 - Difficult to reuse a module because apps don't need all the random operations provided in the module
- Modular design
 - Modular design means high cohesion
 - Each module has clear and related responsibilities
 - Modular design means low coupling
 - Small number of interconnections between subsystems
 - Importance of modular design:
 - 1) Build on a budget!
 - ® Divide up the development and testing work
 - ® Don't have to wait for other parts to be done
 - ® Less time debugging
 - 2) Build maintainable systems
 - ® It is easier to pinpoint the cause of bug to a module and then focus and fix the module
 - ® It is easier to isolate and test before integrating
 - ® It is easier to understand the system as a whole and identify how to add new features
 - 3) Build reliable systems
 - ® You can understand the whole design and identify flaws and fix them
 - ® You can test each part and make sure they work right
- Layered design

- The system modules are organized into layers
- Modules in upper layers are allowed to use the modules in the lower layers
- Examples : operating systems, networking, ..
- Benefits of layered:
 - Managing complexity
 - Maintainability - change in a layer can be hidden and/or substituted
 - A blueprint for constructing the system - specialize developers work on different layers e.g. GUI developers
- Integration Testing
 - V-Model

The V model

- 1) Errors in upstream processes are more expensive to debug and fix
- 2) Higher frequency of errors occurring in upstream processes
 - ® Testers should be involved in requirements and design phase
- Inspections/reviews to trap errors from flowing downstream
- What can you do during reqs?
 - ® Validate
 - ◇ Show prototypes/screen sketches
 - ◇ Design fit-criterion and corresponding acceptance tests
 - ® Verify
 - ◇ Evaluate each requirement for correctness, ambiguity, testability, etc.
- What can you do during arch/coding?
 - ® Design to be testable: controllable/observable
 - ® Plan out top-down and other integration testing mechs
 - ® Logging for debugging
 - ® Checkpointing for debugging
 - ® Preconditions, postconditions, assertions
- Big-Bang Integration
 - After all components are unit tested we test the entire system
 - ® Impossible to figure out where faults occurred!
- Others:
 - Sandwich Integration
 - ® TD and BU meet in the middle
 - Sync & Stabilize Approach
- Bottom-Up Integration Testing
 - Each component at lower hierarchy is tested individually and then the components that rely upon these are tested

Bottom-Up Testing Example

- 1) Test B, C individually (using drivers)
 - 2) Test A such that it calls B
If an error occurs we know that the problem is in A or in the interface between A and B
 - 3) Test A such that it calls C
If an error occurs we know that the problem is in A or in the interface between A and C
- (-) Top level components are the most important yet tested last.

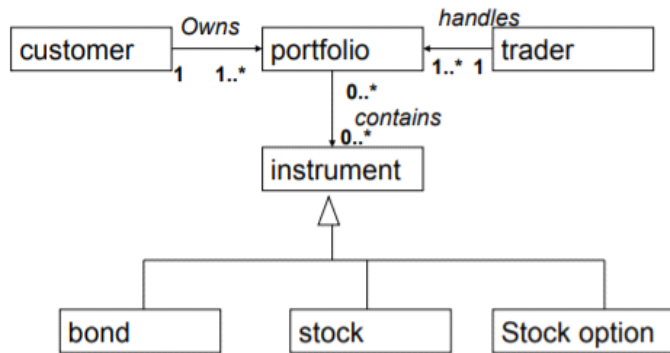

- Top-Down Integration Testing
 - Each component at higher position in hierarchy is tested individually; then the components that they rely upon are tested

Top-Down Testing Example

- 1) Test A individually (use stubs for B and C)
 - 2) Test A such that it calls B (stub for C)
If an error occurs we know that the problem is in B or in the interface between A and B
 - 3) Test A such that it calls C (stub for B)
If an error occurs we know that the problem is in C or in the interface between A and C
- * Stubs are used to simulate the activity of components that are not currently tested; (-) may require many stubs

- Drivers
 - a routine that simulates a call from parent component to child component
 - Used in BU integration
- Stubs/Mocks
 - Stubs: a routine that fakes behavior of a child component
 - Used in TD integration
 - Mockito:
 - A testing tool that helps to create stubs and to verify that calls are made
 - When some method is called- do something
 - Verify that some methods were called to test interactions between methods
- UML
 - Class Diagram
 - Shows classes and their relationships
 - Example:

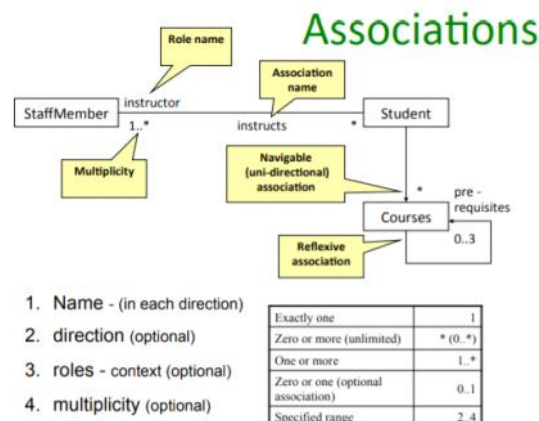

- A class diagram has two types of elements:
 - 1) Class elements

Class element

– three compartments

- ® An attribute is a named property of a class that describes the object being modeled and appear in the second compartment
 - ® Attributes can be:
 - ◇ +public
 - ◇ #protected
 - ◇ -private
 - ® Operations describe the class behavior and appear in the third compartment
 - ® Specify an operation by stating its signature: listing the name, type, and default value of all parameters, and a return type
- 2) Relationship elements
- ® Associations- a broad term that encompasses just about any logical connection or relationship between classes

- ® Aggregation- **has-a** relationship

Aggregation

- Models "has-a" relationship

- Composition -parts whole relationship

Composition

- A stronger form of aggregation
 - The whole is the sole owner of its part.
 - The part object may belong to only one whole
 - Multiplicity on the whole side must be zero or one.
 - The life time of the part is dependent upon the whole.
 - The composite must manage the creation and destruction of its parts.

- Generalization- is-a relationship

Generalization

- is-a

®

- Realization -implements or realizes relationship

Realization

- A realization relationship indicates that one class implements a behavior specified by another class (an interface or protocol).
- An interface can be realized by many classes.
- A class may realize many interfaces.

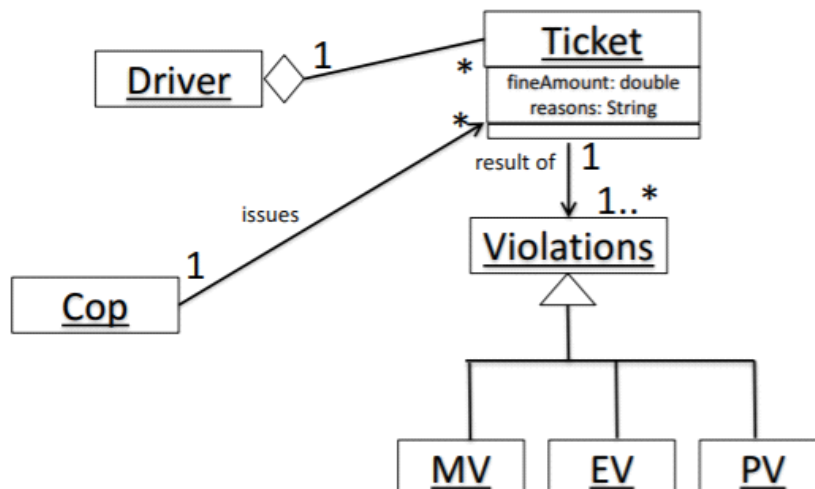

Class Diagram

Draw a class diagram that captures ALL of the information in the below description.

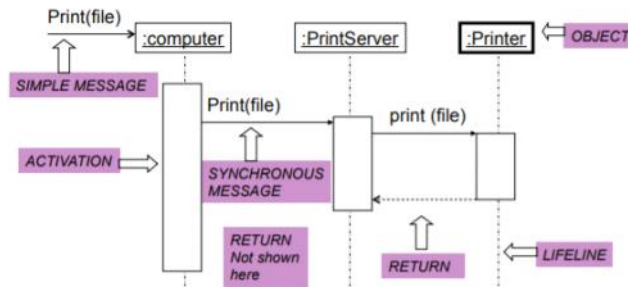

1. A Driver has zero or more active Tickets.
2. A Ticket is a result of one or more Violations.
3. There are three types of Violations: Moving Violations, Equipment Violations, and Paperwork Violations.
4. A Ticket has attributes fineAmount and reasons.
5. A Cop issues zero or more Tickets.

FINAL DIAGRAM

- Sequence Diagram
 - Shows interactions between objects over time

Example Sequence Diagram

- 1) Objects- and not FUNCTIONS

Objects

- Rectangles with object type, optionally preceded by object name and colon
 - write object's name if it clarifies the diagram
 - object's **"life line"** represented by dashed vertical line

Name syntax: `<objectname>:<classname>`

Lifetime of objects

- **creation**: arrow with **'new'** written above it
 - notice that an object created after the start of the scenario appears lower than the others
- **deletion**: an **X** at bottom of object's lifeline
 - Java doesn't explicitly delete objects; they fall out of scope and are garbage-collected

- 2) Activation - only when object's method is on stack (i.e. activated)

Activation: i.e. method calls

- **Activation:** thick box over object's life line; drawn when object's method is on the stack
 - object is running its code, or it is on the stack waiting for another object's method to finish
 - nest to indicate recursion OR to indicate some other method called

- 3) Messages are named
- 4) Correct arrowhead (synchronous vs async)
- 5) Return labeled with value (if needed)

Messages, arrowheads, return messages

- message indicated by **horizontal arrow** to other object
- write message name and arguments above arrow

- different arrowheads for normal / concurrent (asynchronous) methods
- arrow back indicates return (usually dashed)

- Use a frame or box around part of a sequence diagram to show
 - If-then use OPT frame
 - If-then-else use ALT frame
 - Loop use LOOP frame
 - Method use REF frame
- Linking sequence diagrams - if one sequence diagram is too large or refers to another diagram, indicate it with either an unfinished arrow and comment or a ref frame that names the other diagram

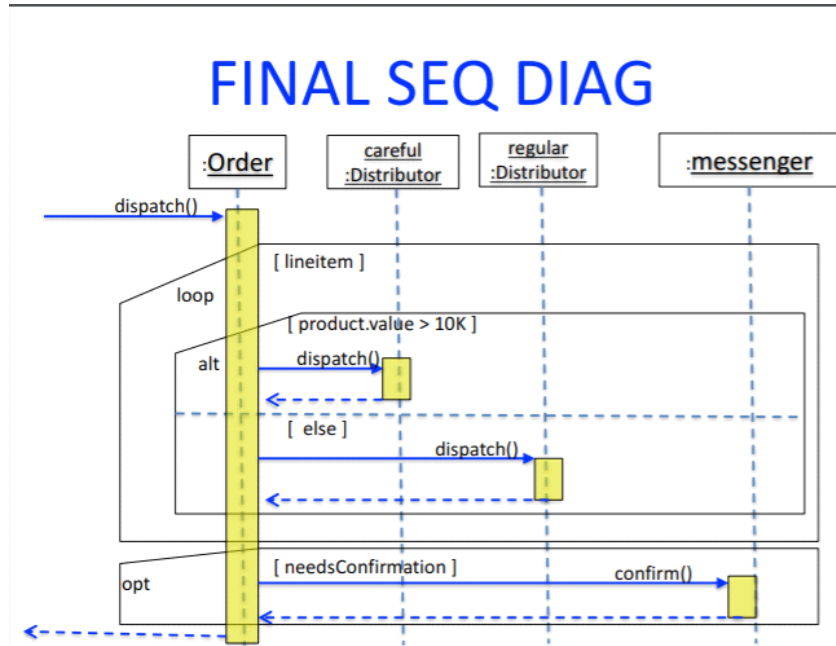

Sequence Diagram

- Draw Sequence diagram for method dispatch being invoked on an Order object (dispatch is a method in class Order). Aside from object Order, there are two Distributor objects (careful and regular), and one messenger object.

procedure dispatch

```
foreach (lineitem)
  if (product.value > $10K)
    careful.dispatch()
  else
    regular.dispatch()
  end if
end for
if (needsConfirmation) messenger.confirm()
end procedure
```

end procedure

- Design Patterns
 - Enables reuse of software design ideas
 - Makes expert knowledge and design trade-offs widely available
 - Helps developer-developer communication by forming common vocab and helps in documentation and enhanced understanding
 - Eases transition to object oriented tech
 - To make code better think of how maintainers, utility developers, application developers work will be effected
- Dependency Inject Pattern
 - 1) Problem
 - Diagram:

APPLICATION	HIGH LEVEL CLASS	LOW LEVEL CLASS
<pre>main() { ... HLC h = new HLC(); h.foo(); ... }</pre>	<pre>class HLC { ... void foo() { ... LLC l = new LLC(); ... l.doSomething(); ... } }</pre>	<pre>class LLC { ... void doSomething() { ... } }</pre>

DIAGRAM-1

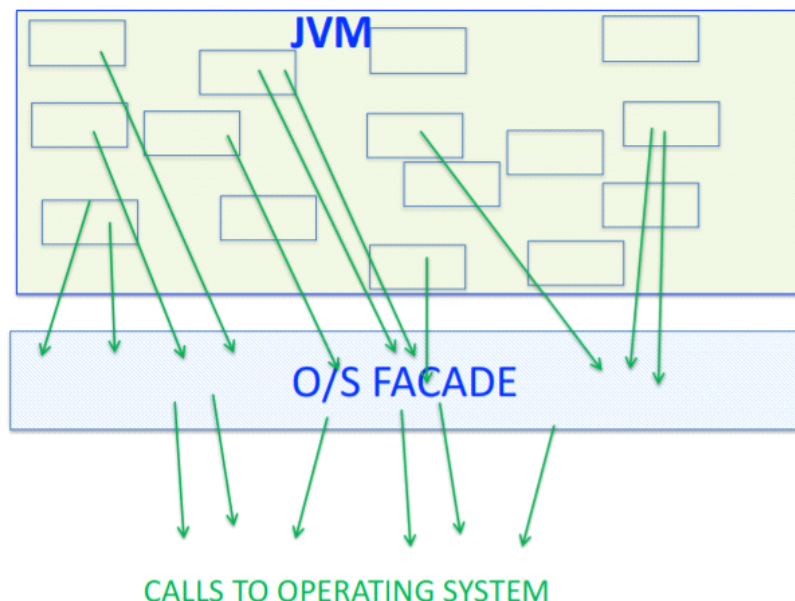

- For maintainers
 - ⊗ HLC has LLC hardcoded
 - ⊗ Changing databases means code needs to be changed
- For testers
 - ⊗ Testing of HLC can't be done without changing source code of HLC
 - ⊗ It is advisable to mock dependent classes to reduce the compile/run/debug cycle

2) Solution

- Diagram:

- Remove the direct dependency between HLC and LLC by introducing an interface
- Inject the LLC object into the HLC code using the HLC constructor
- Façade Pattern
 - Problem is we use #ifdefs in code to change behavior based on OS
 - Time consuming, recompile, retest, more bugs, halt development, not maintainable, messy code
 - Add a new layer that implements the OS façade for each different OS
 - Existing code makes calls to our OS façade instead of #ifdefs
 - Gets rid of #ifdefs, new ports don't need to change code, less errors introduced, less tedious

- Observer Pattern

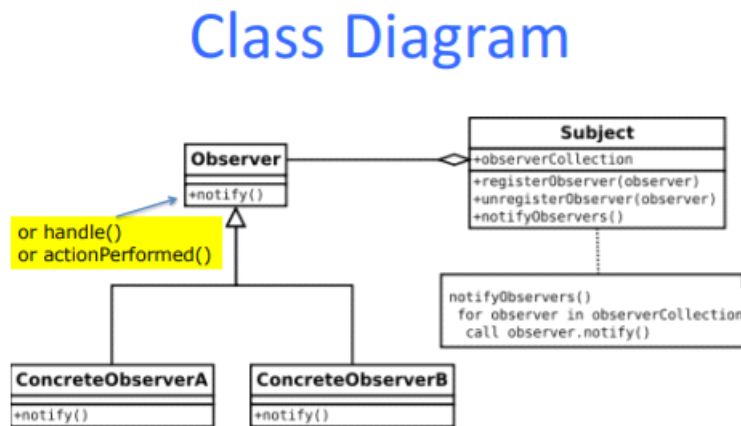

1) Problem

- Given two objects one of them wants to know when something happens to the other
- Ex: line graph wants to know when the table entries are changed
- Subject code should be unaware of specific observers, many observers should be able to observe the same subject, an observer should be able to observe multiple subjects
- It is a bad idea to have subject aware of specific observer because it is hardcoding in class names (not modular), not able to have multiple observers

2) Solution Idea

- Subject has a list of observers (implement observer interface)
- When some change happens a notifyObservers() method is called
- Observers can register/unregister themselves from a subject

3) Class Diagram

8

4) Benefits

- All observers are notified automatically
- Loosely coupled since subject doesn't know about specific observers
- Observers code has no reference to specific subjects
- Many observers on subject, an observer can observe many subjects
- New observers can be added and removed without changing subject code

○ MVC Pattern

- MVC pattern has a model, one or more views, and one or more controllers

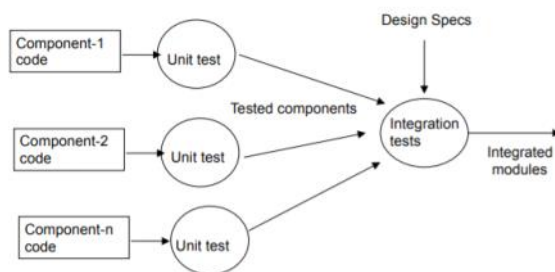

- **Model** - is in charge of storing/managing data
 - Store application data
 - Does not know about the view or controller
 - Provide interface for making changes to the data (set)
 - Notifies views of changes made to data
 - Provides interface for providing access to data (get)
- **View** - is in charge of displaying data
 - Draws or represents the model
 - Responds to changes to model events by registering handlers
 - Loosely coupled with Model
- **Controller** - is in charge of handling user events and controlling model and view operations
 - Registers and acts on user events
 - Updates model
 - Decides application behavior on user action
 - Controller knows about model and view
- **Benefits:**
 - Decouple view and logic from data
 - Separate into modules for separate dev/testing, views can be modified easily, additional controllers easy to add
 - Model can be used with multiple views
 - View can be used for other models too if separated by an interface

Unit: TESTING

Thursday, May 9, 2019 12:02 AM

• Basics of Testing

• Testing Processes

○ Testing Processes

▪ Integration Testing

- Assemble tested components to form the subsystem
- Easier to integrate small pieces and test them than to integrate

- the entire system and then test the whole system
 - ☐ Top-down or bottom-up
- Functional Testing
 - ☐ Test all functionality per requirements
- Performance Testing
 - ☐ Load tests, stress tests, recovery tests, volume tests, etc.
 - ☐ Reliability and usage
- Acceptance Testing
 - ☐ Benchmark tests
 - ☐ Alpha test - pilot test run-in-house
 - ☐ Beta test - pilot test run at customer-site
 - ☐ Parallel testing - both existing and new system run in parallel
- Installation Testing
 - ☐ Running tests at customer site to verify working of installed system
- Issues in Testing
 - Regression testing
 - ☐ After changes have been made in software to check that it doesn't break you have to re-test after changes
 - Testing is not same proving
 - ☐ Goal is to find bugs in a smart way
 - ☐ Exhaustive testing is impossible
 - ☐ Black box- number of test cases/scenarios too large
 - ☐ White box - number of paths too large
 - ☐ There are infinite possible bugs and testing can't show bugs don't exist
 - ☐ More tests don't mean better testing
 - Testing is expensive, effort must be managed
 - ☐ How much percent of overall software development is devoted to testing? A good amount
 - ☐ Testing is an umbrella activity - can start once specifications are defined
 - ☐ Testing involves a lot of work
 - ® Specifying test cases, designing tests, creating tests, ...
 - ® Risk based exercise - balance between cost of testing vs bugs missed
- How do you select testcases?
- How do you judge how effective your tests are?
- How do you automate testing?
 - Automate Testing
 - ☐ Manual testing is expensive and error prone
 - ☐ Automate generate testcase, generate expected, oracle (is answer correct?)
 - ☐ Automated test case generation?
 - ☐ Drivers (JUnit)
 - ☐ Oracles - checks if results are correct

• Test Case Generation

- Blackbox- means you are testing from a functionality point of view, given a function how is it expected to behave
 - 1) You don't have access to the source code
 - 2) You know what the code is supposed to do
 - Check whether it is working ok

- Boundary Value Testing
 - Vary one variable, hold value of rest of variables fixed at a value
 - Check min-1, min, min+1, nominal, max-1, max, max+1
 - Easy to generate
- Equivalence Class Testing
 - Domain partitioned into disjoint classes

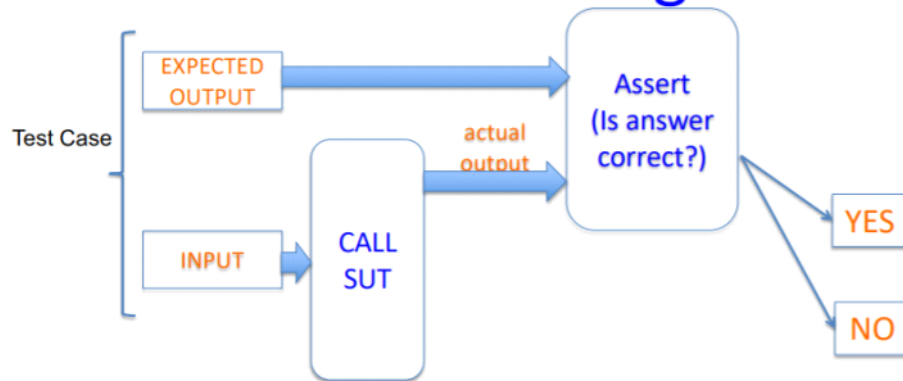

- Each element of domain must belong to one class
 - Testing one element implies testing the whole class since all elements of a class are expected to behave similarly
- Random Testing
 - Generate random tests using operation profile (based on frequency of use during actual operation) as a guide to generate tests
- White Box - look at the source code and test the internal working for defects
 - Take black box tests and test code for coverage then think of more black box tests you may have missed and keep checking code coverage
 - Backtrack and determine inputs that would force tests to execute chosen paths
- Code Coverage
 - Code coverage metrics measure which parts of the code were executed by running all our tests
- Statement Coverage
 - A measure of the percentage of program statements that are run when tests are executed
 - We want to achieve 100 percent statement coverage
- Decision/Branch Coverage
 - Measure of how many decisions have been evaluated as both true and false in the testing
 - Objective is to achieve 100 percent branch coverage
- Condition Coverage
 - Reports the true or false outcome of each Boolean sub-expression of a compound predicate
 - Measures the outcome of each of these subexpressions independently of each other
 - Ensure that each of these subexpressions has independently been tested as both true and false
 - Helps generate tests cases because you find more example test cases that meet the conditions by matching the subexpressions that got missed

- Automation

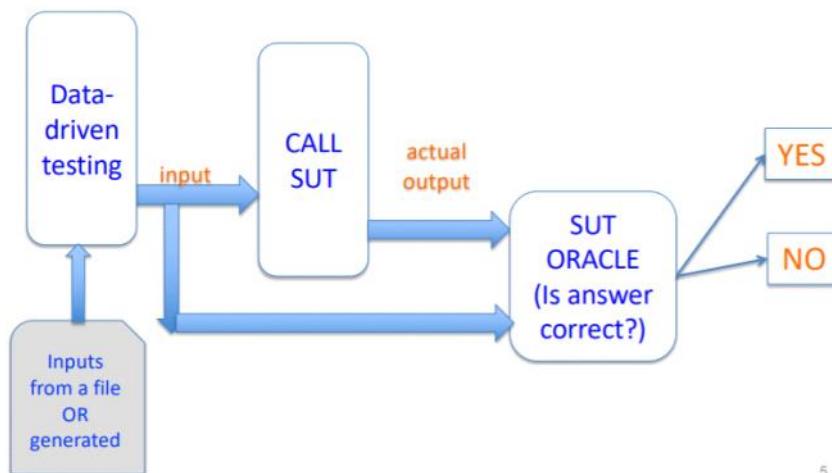

- Creating tests
 - 1) Make a list of test cases (input data and expected result values)
 - 2) Write n test codes for n test cases
 - 3) Run test code
- Automating
 - 1) Generate test data automatically

- 2) Write one test code per function, create an oracle
- 3) Test suites driver

Normal testing

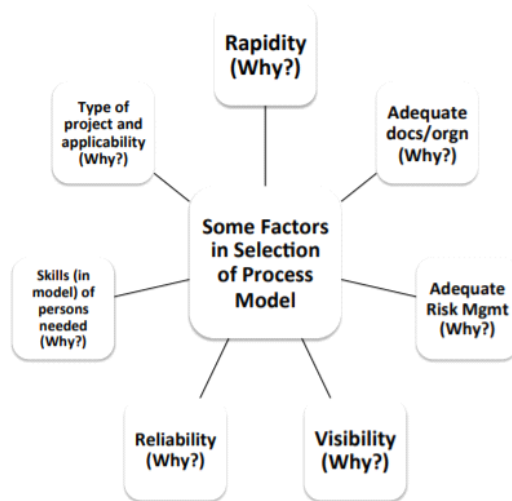

After automation

Unit: PROCESS MODELS

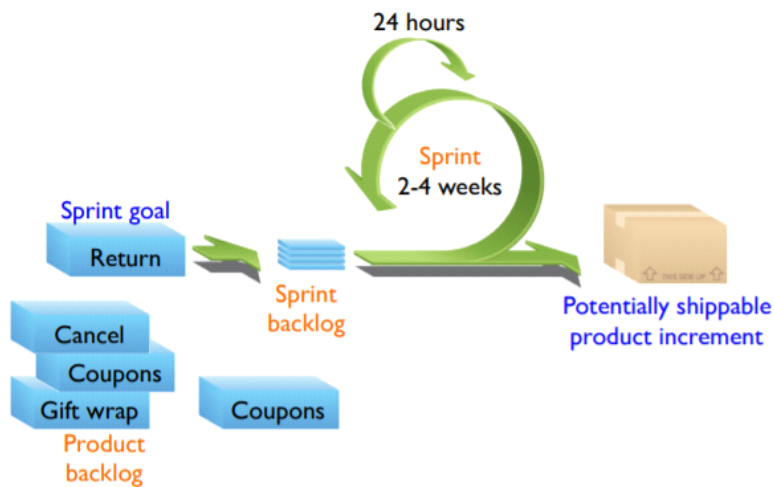

Thursday, May 9, 2019 12:44 AM

- What is a process model?
 - Failure rate for big software projects is 50-75%
 - management know project is likely to fail
 - Millions of dollars spent on abandoned projects
 - Examples: Alaska criminal information database abandoned , Australian census website collapses, Nest thermostat fails to heat homes, etc.
 - Software process models are general approaches for organizing these processes in a project. They prescribe:
 - When to start each process like reqs, design, etc.
 - What is criteria for transitioning between processes
 - They help project manager and their team to decide:
 - What work should be done
 - Task, milestones, deliverables
 - Different projects are handled differently
 - P1: you have to create a binary search program that the customer can use to search info in a data structure
 - Easy to plan accurately and few risks in project - use waterfall approach
 - Define interface, develop code, test code, finalize documentation
 - P2: create a topological sort for the customer
 - Harder to plan, known ways to solve, not risky - use prototype approach
 - Research, play around with algorithm, define interface, develop code, test
 - P3: create a library of different sort programs
 - Known sort algos, obvious increments - use iterative fashion
 - Plan of work divided into phases to develop and release each sorting algorithm
 - P4: sort program that returns results within 1 millisecond for big data
 - Very stringent reqs, many unknowns, very risky - use the spiral/iterative approach
 - Cycle1 - develop an algo and collect data, Cycle2- analyze data and propose solutions, Cycle3- develop a solution?
 - Selection of an approach
 - Choose based on the nature or type of project
 - Ask:
 - Are the reqs clearly defined?
 - Is quality/reliability important?
 - Does it have performance reqs?
 - Is there existing architecture?
 - What is the time-frame?
 - What is skill-level of team?
 - Management point of view
 - Concerns-
 - Visibility, how much work is left
 - Rapidity, time-to-market
 - Reliability, trapping errors
 - risks-handling

- Goals
 - 1) **High quality** software at
 - 2) **Low cost** and a
 - 3) Small cycle **time**
 - 4) **consistently**
- SCRUM process model
 - 1) Scrum Basics

Scrum

- Scrum projects make progress in series of 'sprints'
 - Typically 2-4 weeks
 - Constant duration = better rhythm
 - Product is designed, coded, and tested during each spring
- 2) Scrum Roles
 - Product Owner
 - Define the features of the product
 - Decide on release date/content
 - Responsible for profitability
 - Prioritize features as needed and according to the market
 - Accept or reject results
 - The ScrumMaster

- Represents management
- Enacts the scrum values and practices
- Ensures team is functional and productive
- Enable cooperation between roles
- Shield team from distractions
- The team
 - 5-9 programmers, testers, user experience designers, etc.
 - Self-organizing, full-time

3) Scrum Artifacts

- Product backlog
 - The requirements (user stories)
 - Each item is valuable, prioritized by product owner, reprioritized at start of each sprint
 - Example:

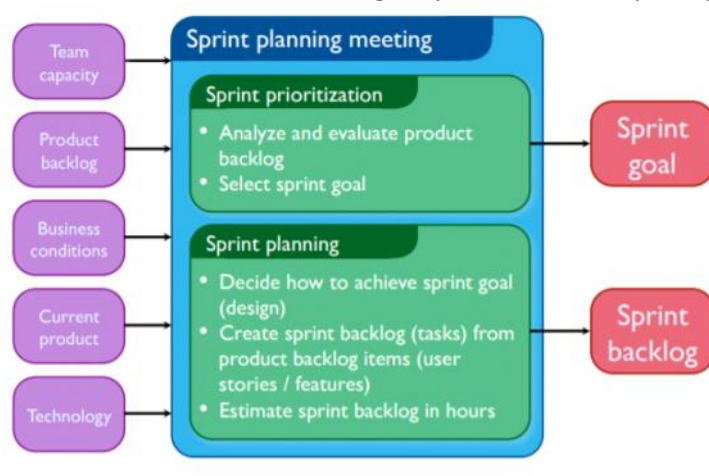

A sample product backlog

Backlog item	Estimate
Allow a guest to make a reservation	3
As a guest, I want to cancel a reservation.	5
As a guest, I want to change the dates of a reservation.	3
As a hotel employee, I can run RevPAR reports (revenue-per-available-room)	8
Improve exception handling	8
...	30
...	50

- Sprint backlog
 - A TODO list selected from the product backlog
 - Estimate hours each task will take
- Scrum Board (Trello)
 - User stories are tasks sorted into to do, in progress, done

4) Scrum Ceremonies

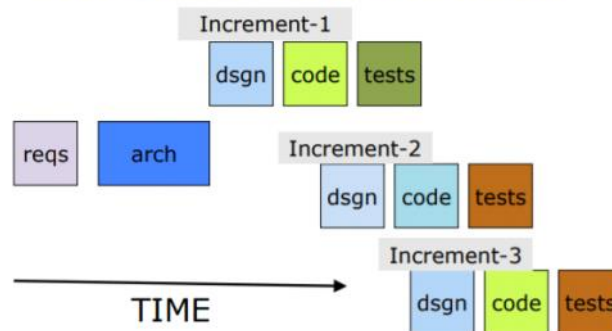

- Sprint planning
 - Team selects items from backlog they commit to completing

- The daily scrum
 - What did you do yesterday? Will do today? Where are you stuck?
 - Not for problem solving, and not status checks
- Sprint Retrospective
 - After every spring gather and discuss what continue doing, stop doing, start doing

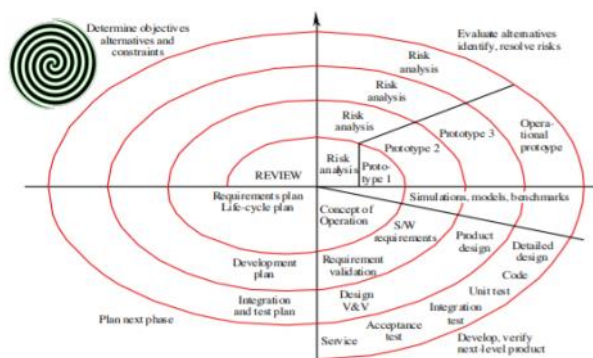

- Sprint review
 - Demo of new features
- Cons:
 - Stressful, anxiety about productivity
 - Herded through small use-cases
- Other process models
 - Code and Fix Model
 - Only for small throwaway assignments
 - Poor reliability, visibility, can't distribute work, messy code, not maintainable
 - Waterfall Model
 - Reqs, architecture, detailed design, coding, testing
 - Linear order of stages
 - Simple to understand and manage
 - Prototyping -waterfall variant
 - Verify reqs with users
 - Try out design alternatives
 - Iterative/Incremental

Iterative/Incremental

- Pros:
 - Quick time-to-market
 - Validate each step with user/feedback
 - Focus on area of expertise at a time
- Cons:
 - Need maintenance and dev teams
 - Messy code
- Boehm's Spiral model
 - Process is a spiral not a sequence
 - No fixed phases, loops are chosen depending on reqs

Boehm's Spiral model

- Pros:
 - Works well with internal software development
 - Clear focus on planning and determining risks/alternatives
 - Flexible
- Cons:
 - Milestones not clear
